The Human Eye

Response of the Human Eye

- The retina of your eye contains both rods and cones to detect the light.
- Cones are sensitive to color, rods are more sensitive to low light levels.
- This is why only the brightest stars show colors.

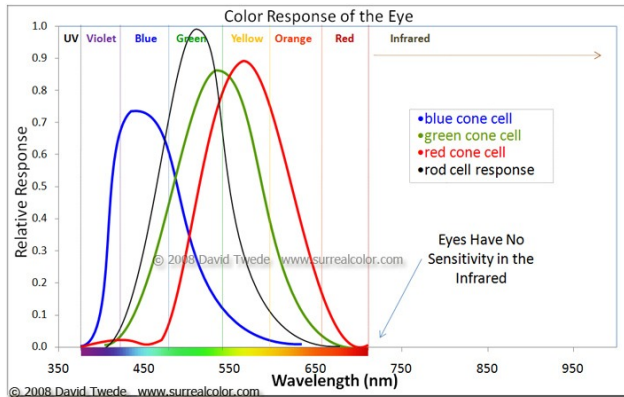

Image Formation by the Eye.

- The lens focuses light from different directions onto different parts of the retina, forming an image.
- The fovea has a much higher density of cones, and a smaller density of rods, so it is less sensitive to dim light.
 - Averted vision (looking off to the side) allows you to see fainter objects.
- In dim light, the iris opens almost completely, and the opening in the pupil is about 7mm in diameter.

Refracting Telescopes

Galileo's Telescope

- (a) Galilean Telescope - Upright Image
(b) Keplerian Telescope - Inverted Image

A Keplerian Telescope

Simplified Refracting Telescope Schematic

- Objects are inverted.
- Magnification $M = f_1/f_2$. Often written $M = f_o/f_e$.

Binoculars

Binoculars are typically referred to with a pair of numbers such as 7 X 50:
7X magnification; 50mm aperture.

Typical binoculars

Binoculars are Keplerian telescopes with a pair of prisms which turn the image right side up.

Chromatic Aberration

- Uncorrected lenses act like prisms and split the light into different colors.
- Making the lens from two different types of glass can correct for this.
- Reflecting telescopes are also free from this *chromatic aberration*.

Reflecting Telescopes

Newton's Telescope

The alt-az telescopes we will use are of this type.

Spherical Aberration

Spherically shaped mirror
has spherical aberration

Mirror with parabolic shape
has no spherical aberration

NOTE: The parabolic shape above has been exaggerated.

- Spherical mirrors suffer from *spherical aberration*.
- Paraboloidal mirrors focus the light to a point.

Coma

- While paraboloidal mirrors are free from spherical aberration, they suffer from *coma*, where images off the central axis are degraded.
- Modern telescope designs correct for both spherical aberration and *coma*.

Types of Telescopes

- (a) Refracting
- (b) Newtonian
- (c) Cassegrain

- (d) Cassegrain-Newtonian
- (e) Schmidt-Cassegrain
- (f) Maksutov

Schmidt-Cassegrain Reflecting Telescopes

Meade Telescope

The Meade telescopes we will use are of this type.

Magnification and Field of View (FOV)

- A higher magnification results in a smaller field of view (FOV).
- True FOV = (Apparent FOV)/M. Most eyepieces have an apparent FOV of $40^\circ - 50^\circ$.
- Typical True FOV of binoculars is $\approx 6^\circ - 8^\circ$.

Why Bigger and Bigger Telescopes - 1?

- There are two main reasons why a bigger telescope is better.
- One - increased light gathering power:
 - A telescope gathers light in proportion to its area.
 - Pupil of eye $\approx 7\text{mm}$ in diameter in dim light.
 - How much more light does the Keck 10 meter telescope gather?

$$\text{Area ratio} = \frac{\pi(10000 \text{ mm})^2}{\pi(7 \text{ mm})^2} = 2.0 \times 10^6$$

- How does this translate into seeing fainter objects?

$$m_{\text{Keck}} - m_{\text{Eye}} = 2.5 \log_{10}\left(\frac{I_{\text{Eye}}}{I_{\text{Keck}}}\right) = 2.5 \log_{10}(2.0 \times 10^6) = 15.8$$

- Since the eye can see to about magnitude 6, since means that the Keck can see to about magnitude 22.
- In practice, Keck can see even fainter (to around $m = 27$), since it uses CCD detectors which are more sensitive than the eye and store light over long periods.

Why Bigger and Bigger Telescopes - 2?

- Two - increased resolution:
 - The resolution of a telescope is its ability to separate two closely spaced objects.
 - The resolution of a circular aperture is limited by *diffraction*, caused by the wave nature of light.
 - The Rayleigh criterion gives the resolution of a telescope. Here:
 - θ is the angular resolution in radians
 - λ is the wavelength of light
 - D is the diameter of the telescope

$$\theta = 1.22 \frac{\lambda}{D}$$

Resolution Examples - 1

- Example 1 - Human Eye in visible light:

- λ is the wavelength of visible light = 500 nm = $5.0 \times 10^{-7}m$

- D is the diameter of the eye = 7 mm = $7.0 \times 10^{-3}m$

$$\theta = 1.22 \frac{5.0 \times 10^{-7}m}{7.0 \times 10^{-3}m} = 8.7 \times 10^{-5} \text{ radians}$$

$$\theta = 8.7 \times 10^{-5} \text{ radians} \times \frac{360}{2\pi} \times 60 \times 60 = 18 \text{ arcseconds}$$

- Example 2 - Keck Telescope in visible light:

- λ is the wavelength of visible light = 500 nm = $5.0 \times 10^{-7}m$

- D is the diameter of the mirror = 10 m

$$\theta = 1.22 \frac{5.0 \times 10^{-7}m}{10m} = 6.0 \times 10^{-8} \text{ radians}$$

$$\theta = 6.0 \times 10^{-8} \text{ radians} \times \frac{360}{2\pi} \times 60 \times 60 = 0.012 \text{ arcseconds}$$

Resolution Examples - 2

- Example 3 - Hubble Telescope in visible light:

- λ is the wavelength of visible light = 500 nm = $5.0 \times 10^{-7} \text{ m}$

- D is the diameter of the mirror = 2.4 m

$$\theta = 1.22 \frac{5.0 \times 10^{-7} \text{ m}}{2.4 \text{ m}} = 2.5 \times 10^{-7} \text{ radians}$$

$$\theta = 2.5 \times 10^{-7} \text{ radians} \times \frac{360}{2\pi} \times 60 \times 60 = 0.05 \text{ arcseconds}$$

- In practice, atmospheric turbulence limits the resolution of the eye to about 60 arcseconds (1 arcminute), and the resolution of the Keck telescope to about 0.5 - 1.0 arcseconds, while the Hubble, since it is in space, comes very close to achieving its theoretical resolution of 0.05 arcseconds.

Resolution Examples - 3

- What are the implications of angular resolution in terms of resolving physical objects?
- Let's calculate the smallest objects we can see on the moon. Remember, for small angles:

$$\theta = \frac{R}{D}$$

$$R = \theta D$$

Resolution Examples - 4

- The distance to the moon D is about 380,000 km, so $D = 3.8 \times 10^8 \text{m}$.
- For the eye:

$$\theta = \frac{1.0 \text{arcminute}}{60} \times \frac{2\pi}{360} = 2.9 \times 10^{-4} \text{ radians}$$

$$R = 2.9 \times 10^{-4} \times 3.8 \times 10^8 \text{m} = 1.1 \times 10^5 \text{m} = 110 \text{km}$$

- For the Keck:

$$\theta = \frac{1.0 \text{arcsecond}}{3600} \times \frac{2\pi}{360} = 4.8 \times 10^{-6} \text{ radians}$$

$$R = 4.8 \times 10^{-6} \times 3.8 \times 10^8 \text{m} = 1.8 \times 10^3 \text{m} = 1.8 \text{km}$$

- For the Hubble:

$$\theta = \frac{0.05 \text{arcsecond}}{3600} \times \frac{2\pi}{360} = 2.4 \times 10^{-7} \text{ radians}$$

$$R = 2.4 \times 10^{-7} \times 3.8 \times 10^8 \text{m} = 92 \text{m}$$

Detectors

- The first telescopes used the human eye as detectors.
- In the 20th century, photographic plates proved much better.
 - They are more sensitive than the eye.
 - They can collect light for long periods of time.
- Today, the CCD (Charged-Coupled Device) imager is the preferred detector.
 - They produce a digitized image that can be read out electronically.

Observatories Across the EM Spectrum

NASA's "Great Observatories"

Spiral Galaxy M101 Spitzer Space Telescope • Hubble Space Telescope • Chandra X-Ray Observatory
NASA / JPL-Caltech / ESA / CXC / STScI ssc2009-03b

The Chandra X-ray Telescope

The Chandra spacecraft

How the grazing incidence mirrors achieve a focus.

The ATC Radio Telescope Array in Australia

Six 22 meter dishes.

Radio Telescope Resolution

- Remember, angular resolution is given by:

$$\theta = 1.22 \frac{\lambda}{D}$$

- What does this mean for radio telescopes?

Suppose $f = 1\text{GHz}$, $D = 22\text{m}$

$$\lambda = \frac{c}{f} = \frac{3.0 \times 10^8 \text{m}}{10^9 \text{Hz}} = 30\text{cm}$$

$$\theta = 1.22 \frac{0.3\text{m}}{22\text{m}} = .014 \text{ radians} = 0.8^\circ$$

- So this huge radio dish, 22 meters across, has a resolution about 50 times worse than your eye in visible light!

LIGO Gravitational Wave Telescope

LIGO Observatory in Louisiana.

LIGO Observatory in Washington state.

The IceCube Neutrino Telescope

IceCube covers a cubic kilometer of ice in Antarctica.

An aerial view of the surface.

Summary

- ① The Electromagnetic Spectrum covers a huge range - from radio waves to gamma rays.
- ② Our eyes are only sensitive to a small part of the EM spectrum.
- ③ Telescopes gather much more light, and have much higher resolving power than our eyes.
- ④ Telescopes in space are probing much more of the EM spectrum, since most radiation does not reach the ground.
- ⑤ We are beginning to probe the universe in other ways than just EM waves.
